

Columns of the Kanban board: Open, In progress, Escalated, Closed. Closed is terminal: no transition reopens it. Every status change bumps version (optimistic locking); claims never touch MongoDB, so they do not reset the SLA clock.

Liveness stays shallow in both states: Kubernetes takes a degraded pod out of the Service but never restarts it. Evicted clients reconnect through the Service, which no longer lists this pod, and rehydrate.

*A crashed or terminated leader does not release the lease: another pod takes over within 15 s plus one tick.
Without a fencing token, a leader paused for more than 15 s may overlap with its successor; the escalation is idempotent.*
